MediFlow AI — Product Brief

The idea

MediFlow AI is an AI copilot for outpatient clinics in Ghana. It writes the clinical note from the consultation, checks it against the clinic's guidelines, reminds patients who are likely to miss follow-ups, and catches NHIS claim errors before submission. A clinician approves every step. It is an AI layer on top of the clinic's existing records system, not a replacement for it.

The pain point

Clinics lose time, patients and money in three places:

- **Doctors are stretched thin.** Ghana has roughly 1 doctor per 8,000 people, and every minute spent writing notes is a minute not spent with patients.
- **Patients don't come back.** About 37% of NHIS-insured hypertension and diabetes patients were lost to follow-up in 2017–2019 NHIA data, often because they didn't know a follow-up was needed.
- **Claims lose money.** NHIS vetting cuts or queries claims for wrong codes, wrong tariffs, uncovered drugs and missing details, on top of already slow payments.

Evidence and sources are in the Validation research tab.

Who it is for

	Who	What they get
Buyer	Owners and managers of private, NHIS-accredited clinics and small hospitals in Ghana	Fewer claim deductions, more completed follow-ups, more patients seen per doctor
Users	Doctors, nurses, front desk, billing officers	Less paperwork; one place to approve notes, care plans, messages and claims
Beneficiary	Patients	Clear instructions in plain English and timely reminders
Showcase audience	Hiring teams for AI developer roles in healthcare	Proof of working LLM, RAG, ML and agent skills on a real problem

What it does

1. **Writes the note:** consultation transcript → structured note with diagnosis code → doctor approves.
2. **Checks the guidelines:** compares each prescription with the clinic's guidelines, with citations.
3. **Plans the next steps:** an AI agent proposes the follow-up, patient message and claim; a nurse approves.
4. **Keeps patients coming back:** predicts who will miss a follow-up and sends them reminders; routes clinical questions to a nurse.
5. **Cleans the claim:** builds the NHIS claim and flags errors before a billing officer submits it.

What we are trying to achieve

Now (prototype): a working, public demo on synthetic data that proves the build end to end, and lands interviews for AI developer roles.

Next (product test): interviews with private clinic owners, doctors and billing officers to confirm the pain and willingness to pay, then a pilot in one clinic.

Goal	Measure	Prototype target
Save doctor time	Notes approved with few edits	Diagnosis and code correct in ≥ 8 of 10 test cases
Keep patients in care	No-show prediction quality	AUC ≥ 0.75
Protect clinic income	Planted claim errors caught	≥ 90%
Stay safe	Actions taken without human approval	0
